## Edge exchangeable models [2], [3]

# Factorizable (“rank one”) paintbox representation

Sequence of edges:  $((3, 6), (1, 5), (1, 7))$

# Factorizable (“rank one”) paintbox representation

Sequence of edges:  $((3, 6), (1, 5), (1, 7))$

# Paintbox representation

Consequences for edge exchangeable models:

- ▶ Rate of vertex arrival gets slower and slower  
⇒ sublinear sparsity:  $\#\text{vertices} = o(\#\text{edges})$
- ▶ Edges pile up  
⇒ linear scaling of degrees:  $d_{j,n} = \Theta(n)$

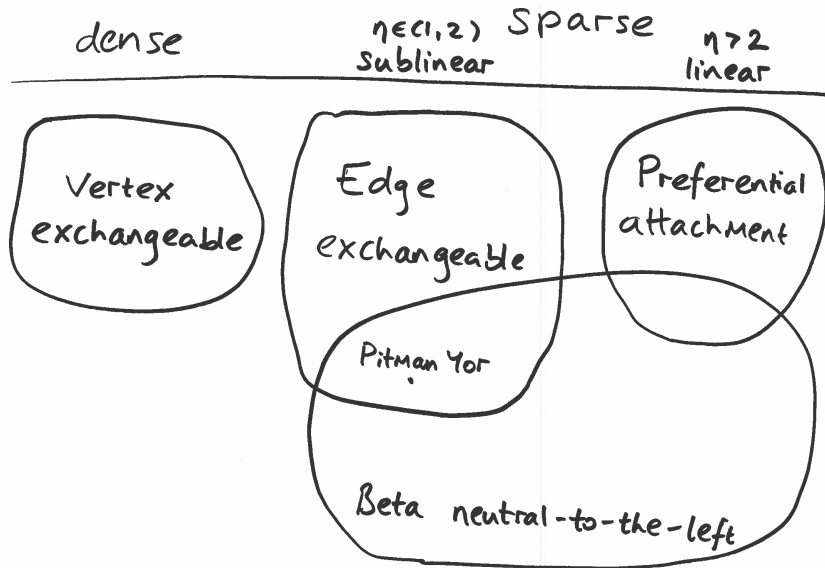

# Models

# Models

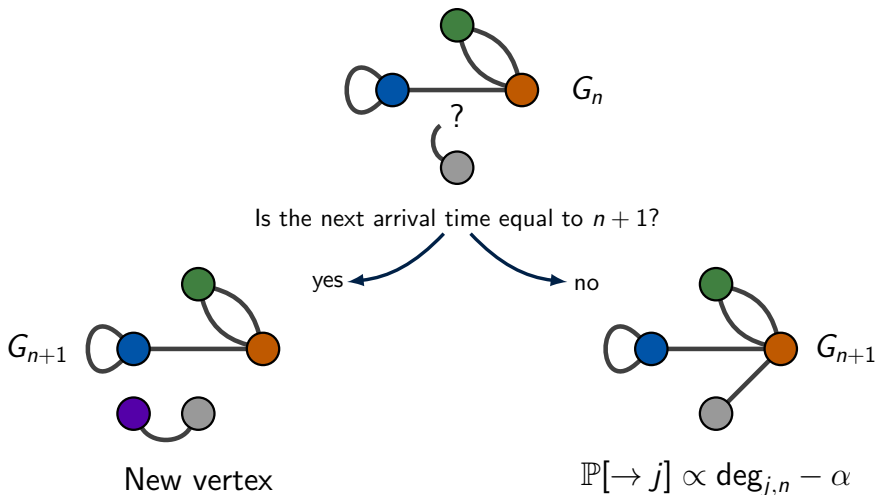

# Models

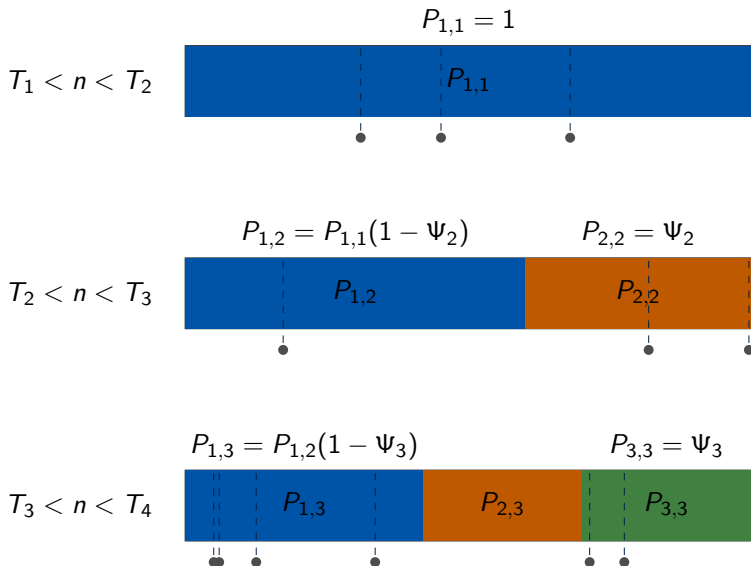

## Beta Neutral-to-the-left Model [4]

1. Generate arrival times  $1 = T_1 < T_2 < T_3 < \dots$  in any way.
2. Generate ends of edges sequentially:

# Sequence of paintboxes representation

# Sampling and inference

Why a paper on sampling and inference for BNTL models?

# Sampling and inference

Why a paper on sampling and inference for BNTL models?

- ▶ Inference is notoriously difficult for *non-exchangeable* structures
- ▶ Need to identify *exchangeable substructures*

# Exchangeable substructure

# Gibbs structure

The joint probability has **Gibbs structure** due to left-neutrality

$$P(\text{graph}|\mathbf{T}) = \prod_{j=1}^K P(\text{choose } j \text{ } d_j - 1 \text{ times out of } n - T_j \text{ trials})$$

- ▶  $K = \#\text{vertices}$
- ▶  $n = \#\text{edges}$
- ▶  $d_j = \text{degree of vertex } j$
- ▶  $T_j = \text{arrival time of vertex } j$

# Gibbs structure

Explicitly,

$$p(\text{graph}|\mathbf{T}) = \frac{\Gamma(d_1 - \alpha)}{\Gamma(n - K\alpha)} \prod_{j=2}^K \frac{\Gamma(T_j - j\alpha)\Gamma(d_j - \alpha)}{\Gamma(T_j - 1 - (j-1)\alpha)\Gamma(1 - \alpha)}$$

- ▶  $K = \#\text{vertices}$
- ▶  $n = \#\text{edges}$
- ▶  $d_j = \text{degree of vertex } j$
- ▶  $T_j = \text{arrival time of vertex } j$

# Available data

Observation	Unobserved variables
Entire history	$\alpha, \phi, \Psi$
Degrees in arrival order	$\alpha, \phi, \Psi, \mathbf{T}$
Snapshot	$\alpha, \phi, \Psi, \mathbf{T}, \sigma$

- ▶  $\alpha$  = BTNL parameter  $\in (-\infty, 1)$
- ▶  $\phi$  = arrival distribution parameters
- ▶  $\Psi$  = latent sociabilities
- ▶  $\mathbf{T}$  = arrival times
- ▶  $\sigma$  = arrival order

# Gibbs sampler

Variable	Gibbs sampling scheme
$\alpha$	MCMC, e.g. slice sampling
$\phi$	Depends on arrival dist. family $\Lambda_\phi$
$\Psi$	$\Psi_j   \text{graph}, \Psi_{\setminus j} \sim \text{Beta}(d_j - \alpha, \bar{d}_{j-1} - (j-1)\alpha)$ where $\bar{d}_j = \sum_{i=1}^j d_i$ can marginalise out $\Psi$
$\mathbf{T}$	Simple update for $T_j$ , can't move past neighbours
$\sigma$	Initialise in descending degree order use M-H with adjacent swap proposal $\sigma_j \leftrightarrow \sigma_{j+1}$ fast to compute due to Gibbs structure

# Point estimation

If entire history observed, **maximum a posterior** (or **maximum likelihood**) estimates for  $\alpha, \phi$  computable

# Experiments

- ▶ Gibbs: parameter recovery
- ▶ Gibbs: scalability
- ▶ Point estimation with massive graphs

# Parameter recovery

- ▶ Simulate 500 edges with fixed  $\alpha$
- ▶ Arrivals either  $\mathcal{PYP}$  or Geom
- ▶ Observe final snapshot of the graph

Gen. arrival distn.	Inference model	$ \hat{\alpha} - \alpha^* $	Pred. log-lik.
$\mathcal{PYP}(1.0, 0.75)$	$(\tau, \mathcal{PYP}(\theta, \tau))$	<b><math>0.046 \pm 0.002</math></b>	<b><math>-2637.0 \pm 0.1</math></b>
$\mathcal{PYP}(1.0, 0.75)$	$(\alpha, \text{Geom}(\beta))$	$0.049 \pm 0.004$	$-2660.5 \pm 0.7$
Geom(0.25)	$(\tau, \mathcal{PYP}(\theta, \tau))$	$0.086 \pm 0.002$	$-2386.8 \pm 0.1$
Geom(0.25)	$(\alpha, \text{Geom}(\beta))$	<b><math>0.043 \pm 0.003</math></b>	<b><math>-2382.6 \pm 0.2</math></b>

# Scalability

- Simulate with fixed  $\alpha$  and  $\text{Geom}(\beta)$  arrivals

	100 edges	10000 edges
$ \hat{\alpha} - \alpha^* $	$0.12 \pm 0.01$	$0.01 \pm 0.00$
$ \hat{\beta} - \beta^* $	$0.02 \pm 0.00$	$0.00 \pm 0.00$
Effective Sample Size	$0.90 \pm 0.04$	$0.75 \pm 0.08$
Runtime (s)	$21 \pm 0$	$2267 \pm 2$

- Runtime linear in #edges
- Most expensive Gibbs update is for  $\mathbf{T}$

# MLEs for SNAP datasets

- ▶ SNAP datasets
- ▶ Fit point estimates for  $\alpha, \phi$
- ▶ Fit: coupled  $\mathcal{PYP}$ , uncoupled  $\mathcal{PYP}$  and  $\text{Geom}(\beta)$  arrivals

# MLEs for SNAP datasets

## Ask Ubuntu

- ▶ Estimates of  $\mathcal{PYP}$  parameters vary significantly between coupled and uncoupled
  - ▷  $\hat{\theta}, \hat{\alpha} = 18080, 0.25$
  - ▷  $\hat{\theta}, \hat{\alpha}, \hat{\tau} = -0.99, -2.54, 0.99$
- ▶ Edge exchangeable models misspecified ( $\eta > 2$ )
- ▶ Using Geom estimates  $\eta$  well

# Conclusion

- ▶ BNTL models are *flexible*
- ▶ BNTL models are *tractable*
